

Assessment 1 - Deliverables

Why Monolith

I chose a monolithic architecture because my project is relatively small in scale and does not require the complexity of a microservices setup. A monolith was easier to design, develop, and deploy since all the core components such as authentication, database access, and business logic are contained within a single service (the API).

All other services inside my docker-compose.yml file, such as PostgreSQL, Elasticsearch, Prometheus, Grafana, Kibana and Nginx where all supporting tools. None of those tools have some kind of business logic of the application. These tools only assist the API service.
